characteristics of microwave signals. An electromagnetic wave does not travel in a straight line: the wave spreads out as it propagates. Also, the individual waves that make up a radio signal do not travel at the same phase velocity. A French physicist, Augustin Fresnel, defined the propagation of a radio

An Introduction to Microwave Radio Link Design

The evolution of radio from what is now known as 0G, for early radio, through to 6G, for sixth generation cellular radio, is used to present modern microwave and RF engineering concepts. Two key themes unify the text: 1) how system-level decisions affect component, circuit and subsystem design; and 2) how the capabilities of technologies, components, and subsystems impact system design.

essential in our modern society. Microwaves are electromagnetic waves[1] generally defined as lying within the frequency range of 100 MHz (3 m wavelength) to 300 GHz[2] (1 mm wavelength).[i] Above 30 GHz, because wavelengths are measured in mm, it is the convention to call them mmWaves.

Most often it is the dielectric constant ϵ_r that is most important in microwaves. For electromagnetic radiation, the permittivity of the medium that the wave is propagating in is equal to $\epsilon_r \epsilon_0$. In a vacuum or in dry air, ϵ_r is equal to unity, and the signal travels at the speed of light.
