In this paper, we propose a device-free wireless localization system using Artificial Neural Networks (ANNs). The system consists of two phases. In the off-line training phase, Received Signal Strength (RSS) difference matrices between the RSS matrices collected when the monitoring area is vacant and with a professional in the area are calculated.

A coal mine wireless sensor network is constructed in underground mines based on the ZigBee technology. Non-metric MDS algorithm is introduced into the estimation of the reference nodes' location, which provides higher fault-tolerance ability. An improved SBL algorithm, N-best SBL, is proposed to improve the localization accuracy.

Wireless based indoor localization uses features of received signal to infer the distance to known points and get the location of current point. Most of current works in indoor localization uses wireless based indoor localization.

Survey of Wireless Based Indoor Localization Technologies

First, we convert wireless signals received at multiple antennas on an access point to a physical parameter, like the angle of arrival of the signal. This transform is independent of any environmental variables, and is (in most cases) a change of signal representation performed using some variant of the Fourier transform.
